## Motion

### (i) Distance ( $\alpha$ )

Case-I

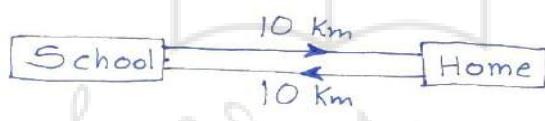

### (ii) Displacement ( $s$ )

$$\alpha = 20 \text{ Km}$$

$$s = 10\sqrt{2} \text{ Km}$$

Case-II

$$\alpha = 10 + 10 = 20 \text{ Km}$$

$$s = (+10) + (-10) = 0 \text{ Km}$$

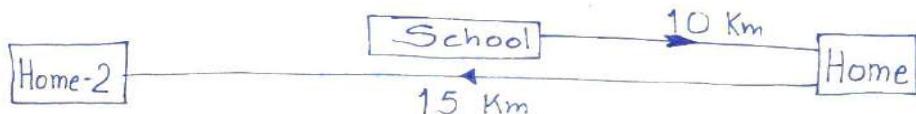

Assuming right side to be (+ve)

Assuming left side to be (-ve)

This assumption is known as 'Frame of Reference'.

Case-III

$$\alpha = 10 + 15 = 25 \text{ Km}$$

$$s = (+10) + (-15) = -5 \text{ Km}$$

Vectors: Quantities which represent opposite direction if signs get changed from +ve to -ve.

Scalars: Usually, what is not a vector is a scalar.  
'Frame of Reference' is valuable only for vectors.

(iii) Speed  (The value on speedometer)

(iv) Velocity =  + Direction

Speed  
Scalar

Velocity  
Vector

Direction of velocity is tangential to the motion.

(v) Acceleration = Rate of change in velocity

Jeep 0 Kmph to 60 Kmph in 15s

Ferrari 0 Kmph to 60 kmph in 3s

Change in velocity is same but rate is different

- In layman terms, acceleration is 'pickup' of a vehicle.

by 3 ways

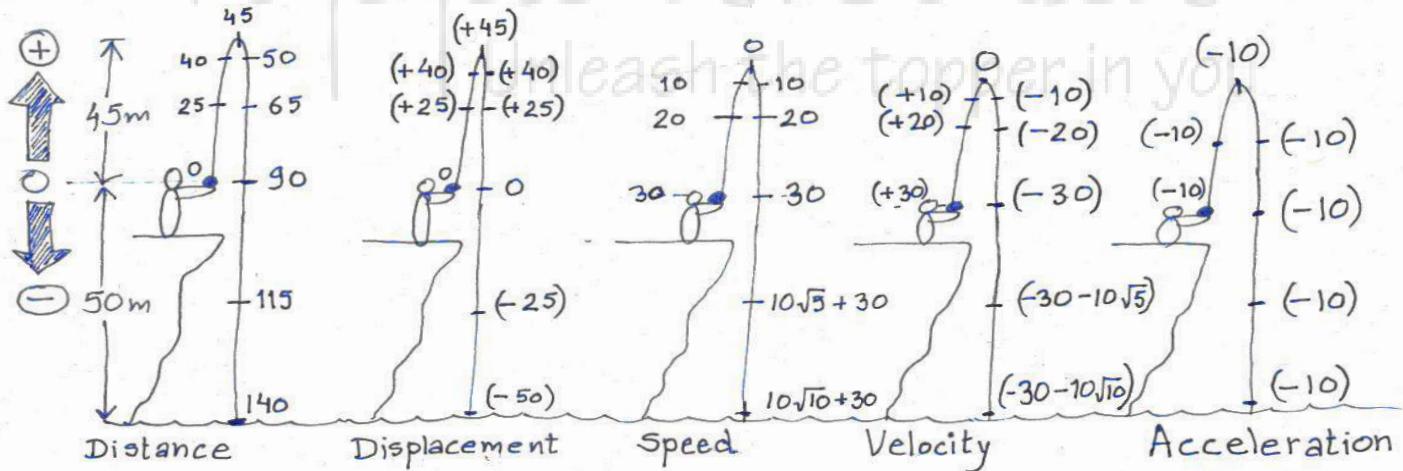

velocity - change.

- ★ Direction of displacement tells, which side the object is.
- ★ Direction of velocity tells, which side the object is going.
- ★ Direction of acceleration tells, which side the object is experiencing a force.

The direction of acceleration is always towards the applied force.

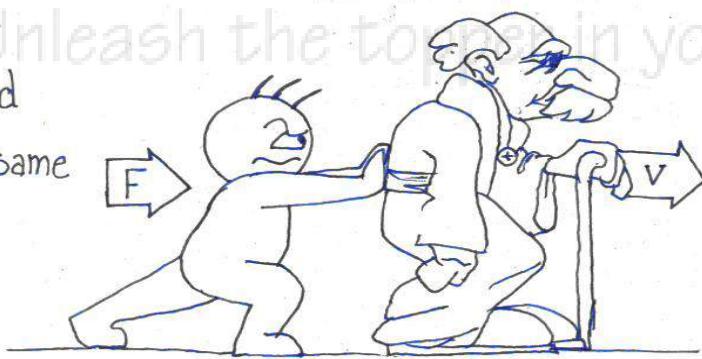

Distance is the value on odometer.  
while speed is the value on speedometer.

## The grand table

Case	Angle	Diagram	Direction
 	$0^\circ$		
 	$180^\circ$		
 	$90^\circ$		

### Case 1 :

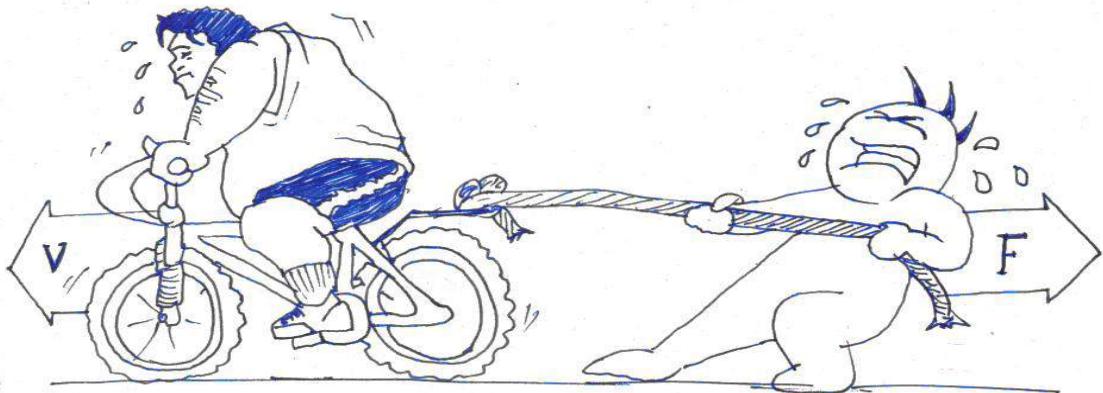

When 'velocity' and 'Force' are in the same direction

Important note: If a body moving in  $+x$  direction starts going in  $-x$  direction later, mathematically it is not referred as a direction change as the body is still on the same axis.

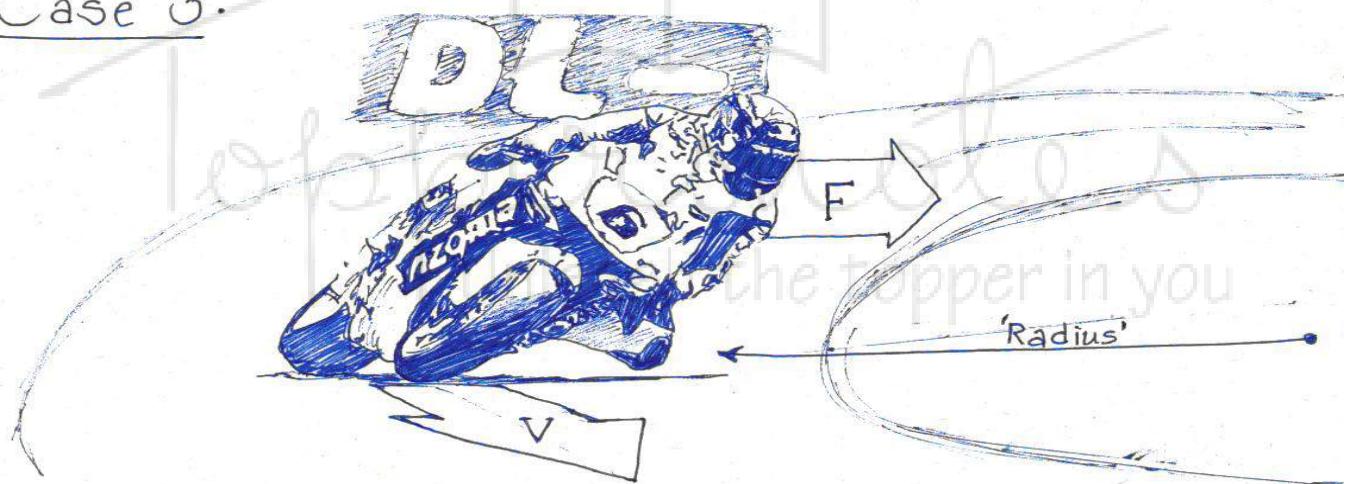

Direction changes if axis changes, like  $x$  to  $y$  or  $z$ .

### Case 2:

When 'velocity' and 'Force' are opposite.

### Case 3:

Force (inwards the radius) is perpendicular to velocity (tangential to the curvature)

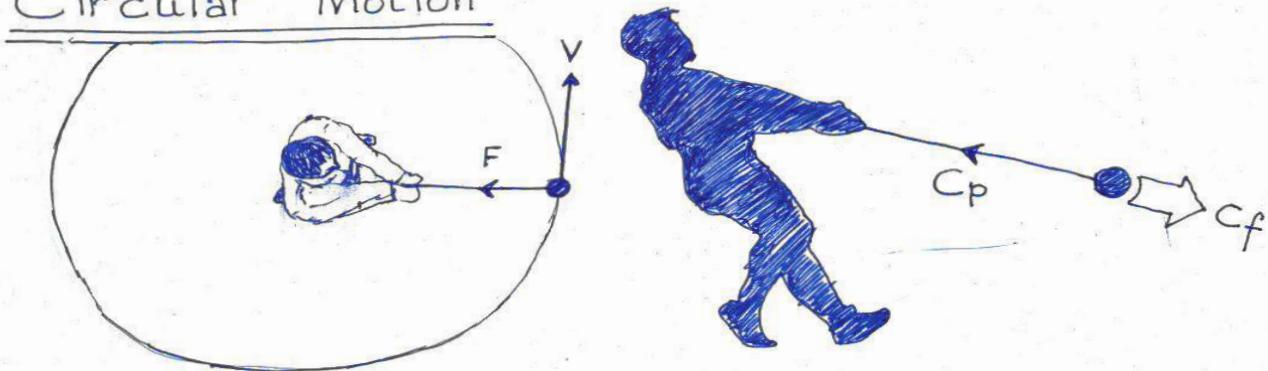

Forces may be of many types. Various forms of force depicted in these examples are:

Case 1 : Contact force (Normal reaction)

Case 2 : Tension force of string

Case 3 : Contact force (Friction)

## Circular Motion

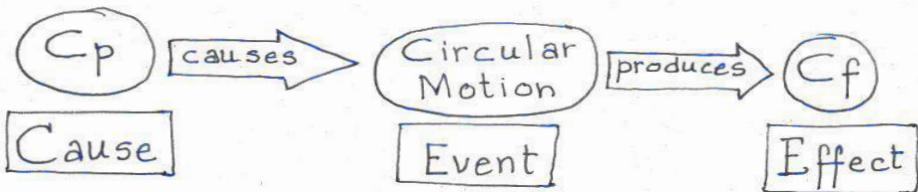

Centripetal force : Towards the center

- : Responsible for circular motion
- : Perpendicular to velocity

As there is this force ( $C_p$  now onwards), so there is acceleration. Hence, every circular motion is an accelerated motion.

Centrifugal force : Away from center

- : Effect of circular motion
- : Perpendicular to velocity

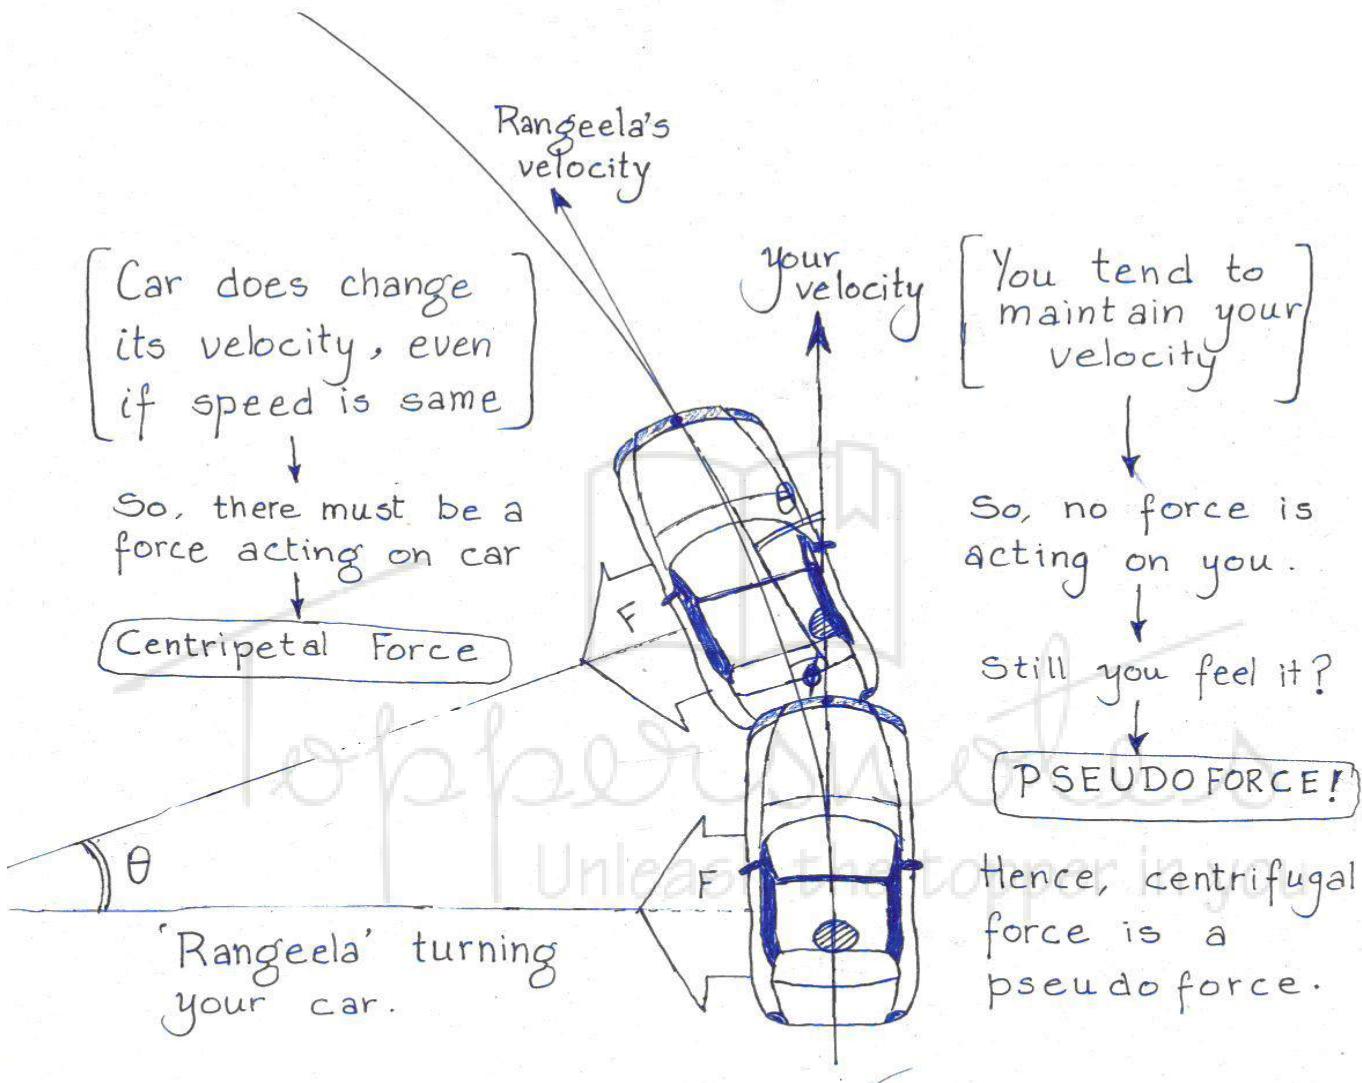

These forces are equal in measurement (i.e. Magnitude)

$C_p = -C_f$

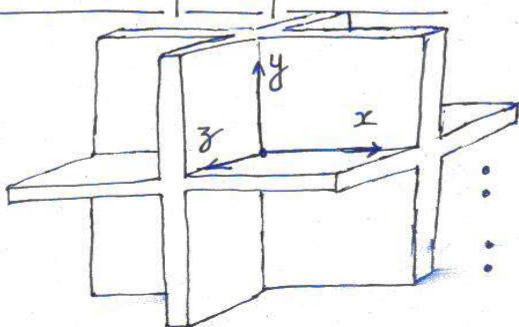

Still!! They are not an example of "Action - Reaction - Pair"

But they are opposite in direction

## Origin of Centrifugal force

### Frame of reference :

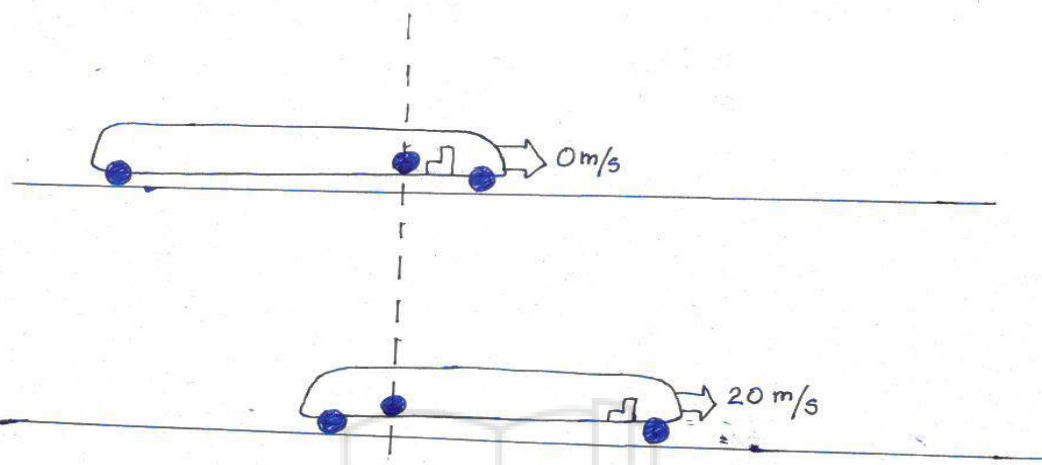

The arbitrarily chosen origin & the axes in space, from where measurement is done

Useful only in vectors

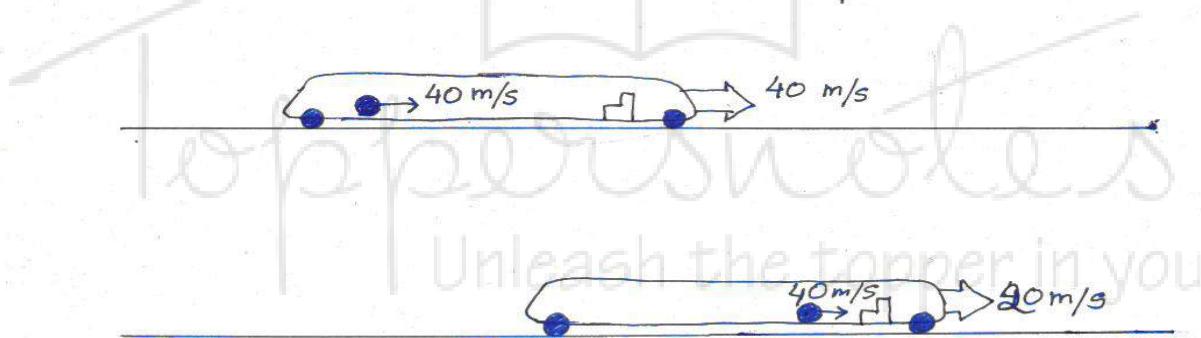

In short, it is a man observing motion with (i) a meter rod & (ii) a stop watch.

Pseudoforces are of 3 types

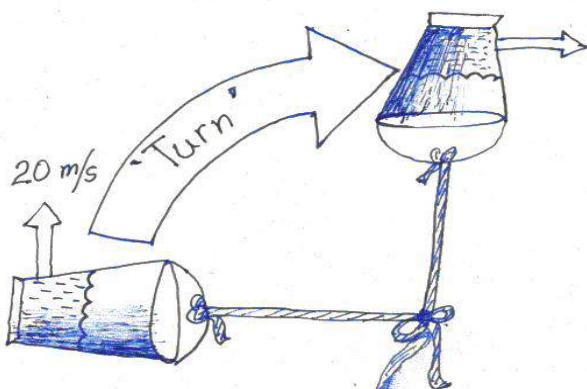

(i) Due to increasing speed of environment

(ii) Due to decrease in speed of environment

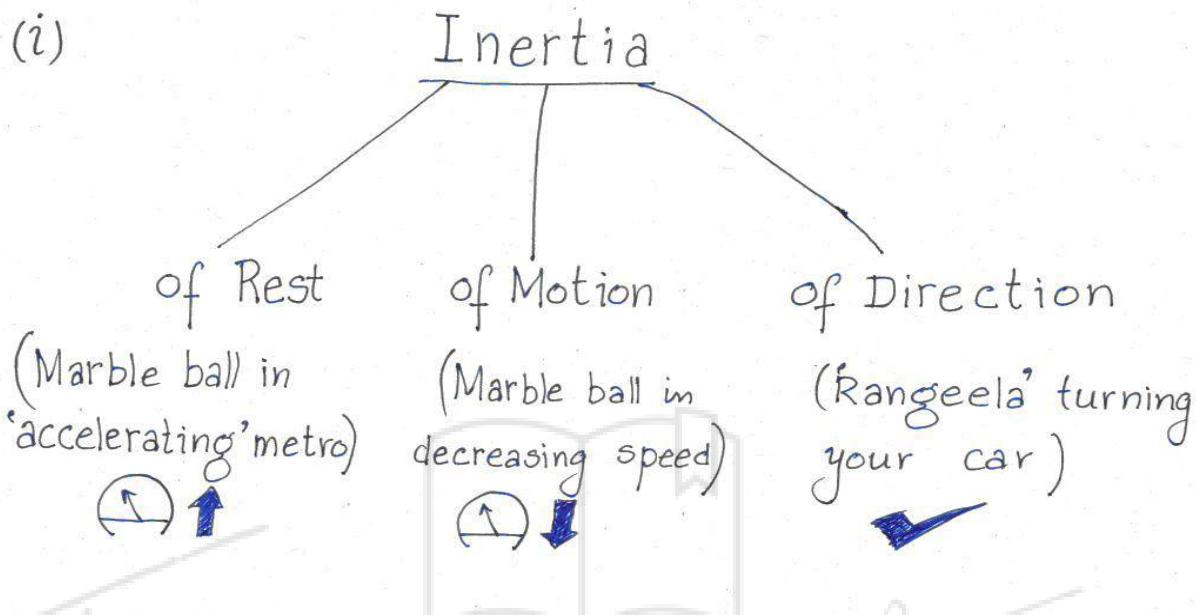

(iii) Due to change in direction of motion of environment

Pseudoforces form  
the basis of  
'Inertia'

## Newton's laws of Motion

(i)

Condition to check the Law of Inertia (or the Law of conservation of linear momentum) is that external force must be zero.

(ii)

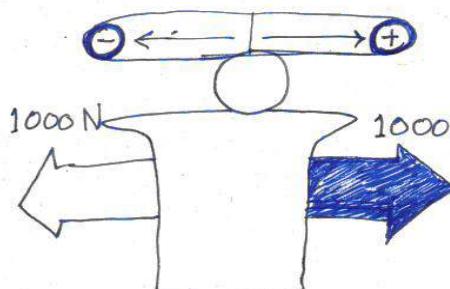

$$F = ma$$

$F$  = force  $\rightarrow$  if  $F=k_1$ ,  $m \propto 1/a$

$m$  = mass  $\rightarrow$  if  $m=k_2$ ,  $F \propto a$

$a$  = acceleration  $\rightarrow$  if  $a=k_3$ ,  $F \propto m$

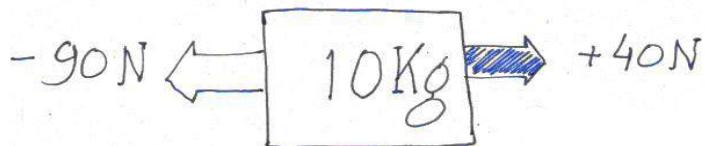

$k$  = constant

$$F \neq 2000 N$$

$$\begin{aligned} F &= (+1000 N) + (-1000 N) \\ &= 0 N \end{aligned}$$

Hence force is a vector quantity

$$F = m \cdot a$$

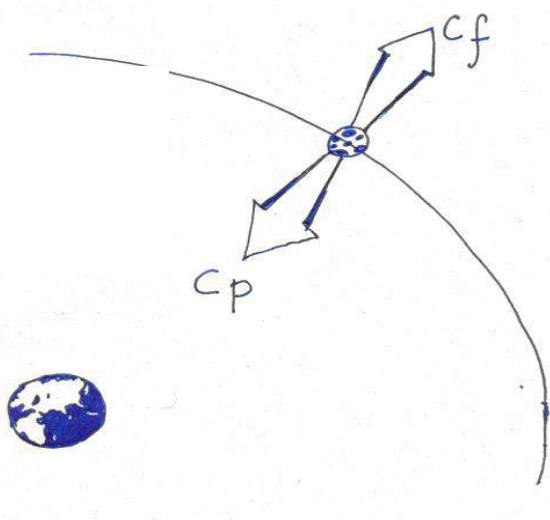

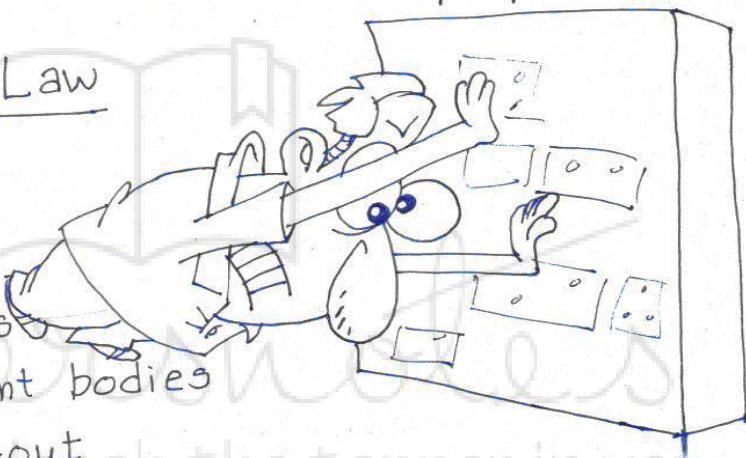

$$-90 + 40 = 10 \cdot a$$

$$-50 = 10 \cdot a$$

$a = -5$  Hence direction of acceleration is same as that of force.

### (iii) Action-Reaction Law

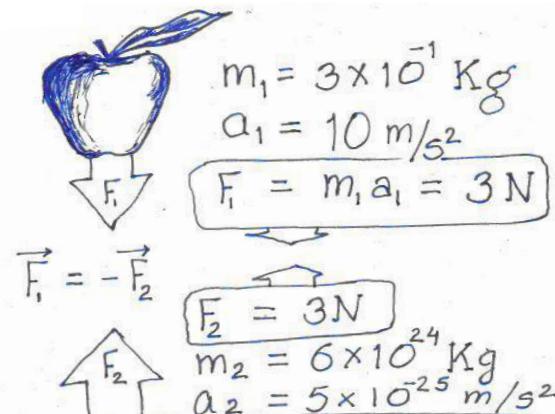

- (i) Equal
- (ii) Opposite
- (iii) Simultaneous
- (iv) Act on different bodies
- (v) Never cancel-out
- (vi) Act on same surface (if contact forces)

Moon rotating around earth

- (i)  $C_p = C_f$  in magnitude
- (ii)  $C_p$  is opposite to  $C_f$

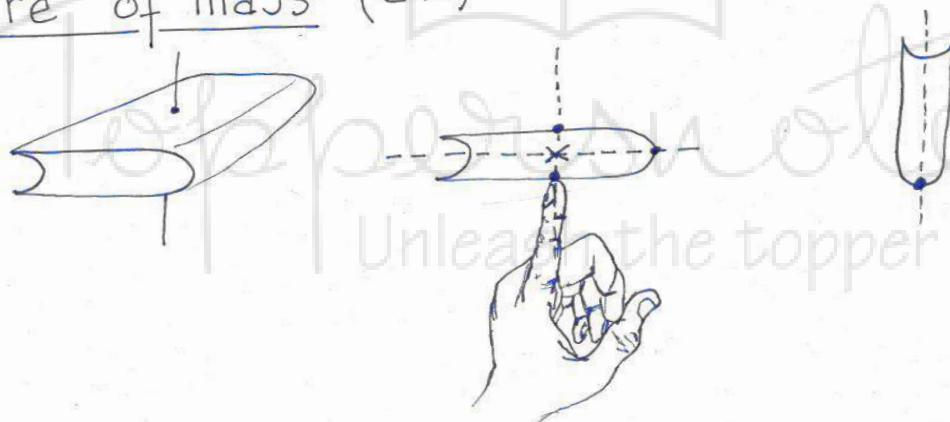

Still  $C_p$  &  $C_f$  do not make action-reaction pair because both  $C_p$  &  $C_f$  act on same body i.e. the Moon.

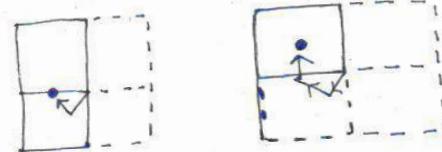

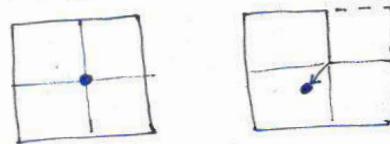

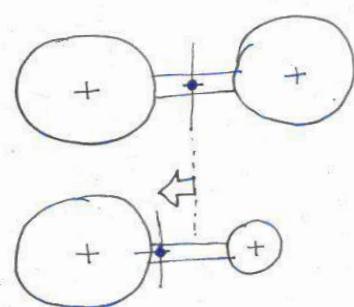

$$\therefore a_2 = 0.\underbrace{000000000000000000000000}_{24 \text{ zeroes}}5 \text{ m/s}^2$$

Hence, earth also bounces upwards as apple falls.  
But acceleration is too low to make it observable.

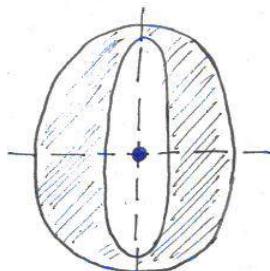

### Centre of mass (c.m.)

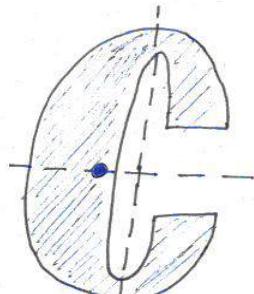

c.m. shifts towards heavy part of the object

It is not necessary that material is also present at centre of mass.

Symbol of  
opera mini

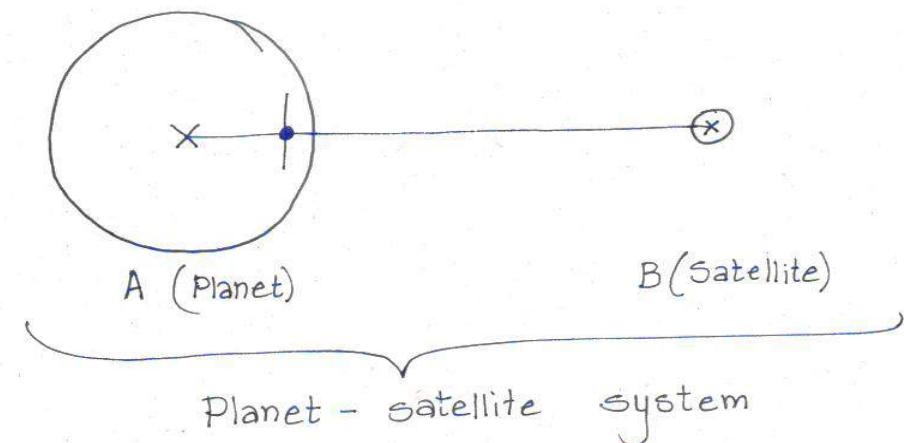

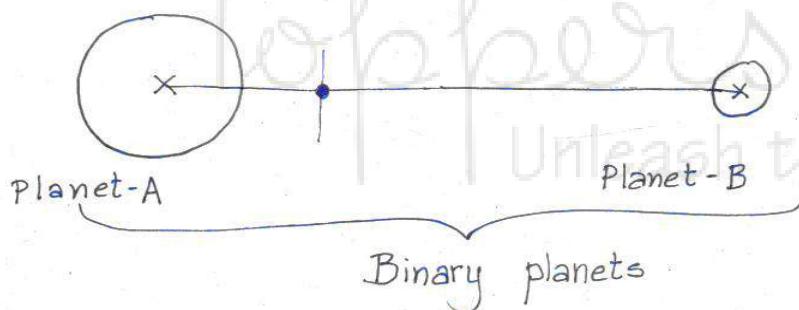

'C'-shape

A 'T-T' ball

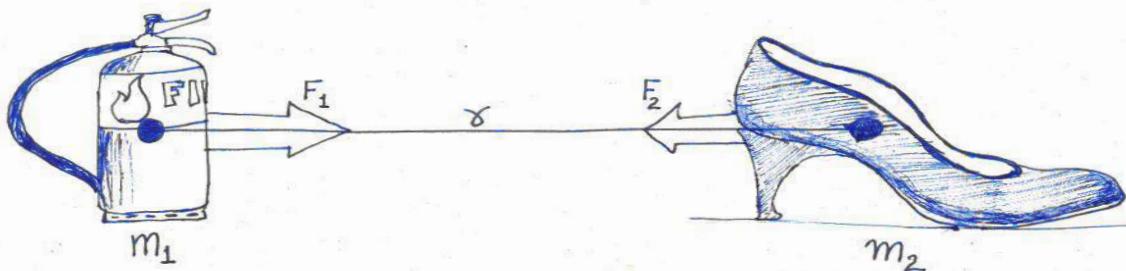

(no plastic is present at c.m.)

Concept of planets and satellites

B (Satellite)

## Gravitation

Any two objects attract each other due to mass in them with forces  $F_1$  &  $F_2$  &  $F_1 = F_2$  always.

- \* ' $r$ ' is the centre to centre gap between objects
- \* ' $m_1$ ' & ' $m_2$ ' are respective masses of objects.

Thus,  $F_1 = F_2 = F = \frac{G m_1 m_2}{r^2}$

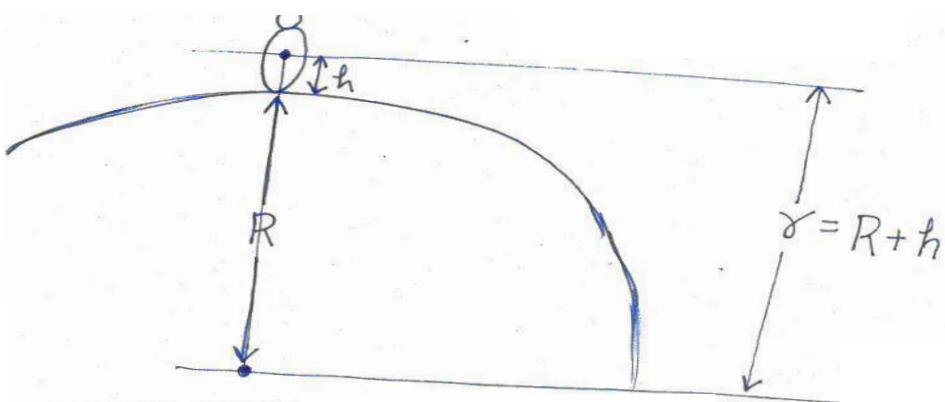

$$F_1 = m_1 a_1$$

$$F_2 = m_2 a_2$$

- \* ' $G$ ' is known as gravitational constant.

$$G = 6.67 \times 10^{-11} \text{ Nm}^2/\text{kg}^2$$

## Acceleration due to gravity

$$F = \frac{G m_1 m_2}{r^2}$$

$$m_1 a_1 = \frac{G m_1 m_2}{r^2}$$

$$a_1 = \frac{G m_2}{r^2}$$

Thus,  $a_1$  is independent of mass of object,  $m_1$ .

That's why, two objects released from same height

- in vacuum
- simultaneously

reach earth together

- even if mass is different

So, it doesn't matter if you drop an elephant or a mouse  
 $\therefore$  we no need to calculate  $a_1, a_2, a_3$  etc. We  
 replace them all with common symbol 'g'.

Now,

$$g = \frac{G m_2}{r^2} = \frac{G m_{\oplus}}{(R+h)^2}$$

$$= \frac{(6.67 \times 10^{-11}) \times (6 \times 10^{24})}{((6.4 \times 10^6) + (0.5))^2}$$

All values in SI units

$$\approx 9.8 \text{ m/s}^2 \quad (\text{by ignoring little value of } h=0.5\text{m})$$

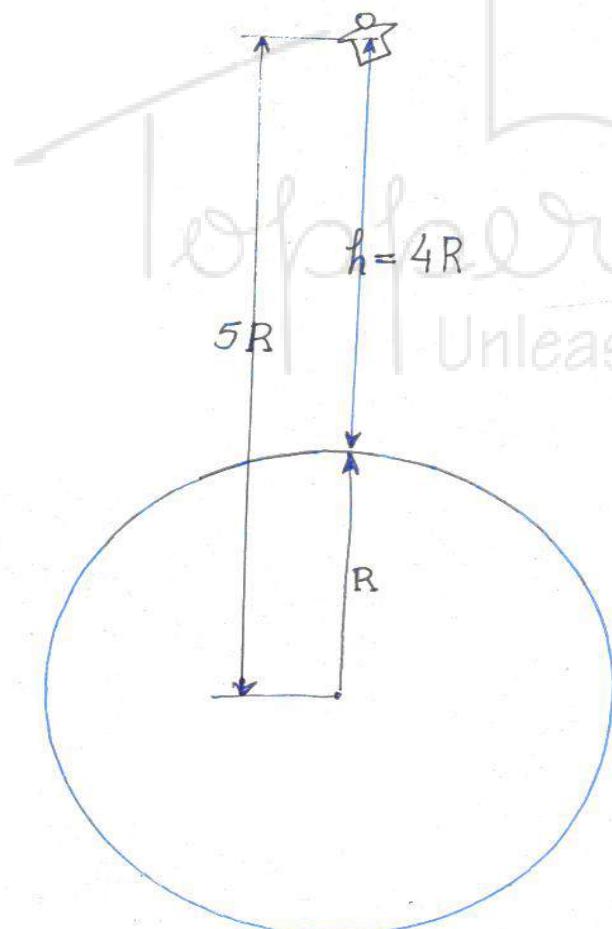

$\therefore g = 9.8 \text{ m/s}^2$  only if object is very close to the surface of earth. But value of 'g' changes as we go very deep inside the earth OR  
 ● very high above earth's surface.

$\therefore$  if depth (d) or height (h) is comparable to the radius of earth, it can not be ignored and it affects the value of 'g'.

## Effects on gravity

- 1) due to height
- 2) due to depth
- 3) due to rotation of earth
- 4) due to shape of earth.

## Effect of height

$$F = \frac{G m_1 m_2}{r^2} = \frac{G m_1 m_2}{(R+h)^2}$$

if  $h = 4R$ ,  $F' = \frac{F}{25}$

$$g' = \frac{g}{25}$$

if  $h = \infty$ ,  $F' = \frac{F}{\infty^2} = 0N$

$$g' = \frac{g}{\infty^2} = 0 \text{ m/s}$$

Hence, 'g' decreases with ~~is~~ increasing height & reduces to zero at infinity.
